Abstract: The n-octanol/water partition coefficient (log Kow) is a key parameter in chemical environmental studies as it determines the environmental fate and bioavailability and thus toxicity of a compound. Due to their unique properties, measurement of log Kow values of surfactants is a technical challenge. The traditional ‘shake-flask’ method (OECD 107) is no longer considered appropriate. Here we compare log Kow values of surfactants were compared using a range of existing experimental and predictive methods which have been used by lead registrants in REACh phases 1 and 2. However, there are concerns that these methods have not been fully validated for surfactants and may not be applicable due to the specific phase behaviour of surfactants, leading to unreliable or unrealistic values. This is complicated by the fact that the solubility is not properly defined for surfactants since they will form a micellar phase above the Critical Micelle Concentration (CMC) up to relatively high concentrations. In the light of this, log Kow values were generated for a select set of 12 surfactants. Side-by-side comparisons of values derived using different experimental methods compared against predicted values identified whether certain existing methods give similar results for the same surfactants and recommendations made.
